Abstract: 
Nowadays power generation by means of renewable energy resources are more common. Renewable energy resources does not cause any problem to the environment. This paper mainly focus on wind and solar energy for generation of power. Since wind and solar energy both are renewable energy resources. Power generation by means of solar and wind energy both in combined named as hybrid power generation. Wind and solar energy are unstable in nature. But wind and solar energy are the best method to provide or to satisfy the load demand. Power generation by means of combined wind and solar energy. Called hybrid system will be more useful to supply remote communities. However these remote communities does not connected with power grid. These areas are named as off-grid or stand alone power supplies. Number of villages in this world are still excld from power these villages are energized by means of extended grid or by diesel generators. But diesel generators are uneconomical. In order to reduce the cost of generation of power to meet the load requirement focused on wind and solar energy for generating electrical energy. By using the combination of solar and wind energy resources we also reduce the usage of fossil fuels. Generating electrical energy by means of renewable energy resources will have many advantages. It is economical, non polluting, not depletable.Generating electrical energy comprise of the following blocks. The blocks are wind energy turbine, photo voltaic observer, to save energy battery, converters, finally to three phase inverter circuit with load. This paper mainly focus on switching or triggering method of 30 inverter here we used space vector pulse width modulation technique.

Keywords: SVPWM, Modified SVPWM, Hybrid system, Diesel generators.

1. INTRODUCTION

In order to reduce greenhouse effect and global warming. We introduce a new method to generate electrical energy. That is hybrid system (Both wind and solar energy) method of generating power. Its very familiar nowadays, integration of wind and solar energy.[1][2] It is Economical,
performance characteristics we carried out simulation.

2. DESCRIPTION OF HYBRID RENEWABLE ENERGY SCHEMES

In order to meet the load demand in off-grid areas or standalone loads hybrid systems are designed. Most accepted hybrid systems includes the combination of wind and solar energy. But wind and solar energies are not available at all time and at all periods. Below black diagram represents the format of hybrid renewable energy generation.[5][6]

PV Module is used to observe the solar radiation as much as maximum as possible. The PV module comprise of number of solar cells or photovoltaic cells. On the other hand wind energy is observed by means of wind generators. Both renewable energy resources are being saved by battery as DC source. We need AC source to drive motor so DC is converted by means of inverter circuit. Switching of inverter are the another problem. Traditional space vector pulse width modulation method are used for switching the inverter circuit. But this method have several disadvantages like unbalanced operation complication in switching. To avoid the disadvantages. This paper concentrates on space vector pulse width modulation for switching the inverter circuit. This system avoids the disadvantages of traditional method. It also have the advantages like harmonic distortion is less and also have good performance characteristics. After getting the output from inverter circuit it is fed directly to load circuit to meet the demand.[5][6] Number of villages and remote communities will get power by means of this renewable hybrid energy systems.

In this research work a novel approach for hybrid renewable energy system (By wind and solar) is proposed. Switching method for inverter is space vector pulse width modulation and it is compared with traditional space vector pulse width modulation. The below figure shows the overall methodology of hybrid system (with solar and wind) with grid connected for load.[7] traditional space vector pulse width modulation technique.

3. SOFTWARE SIMULATION – FPGA TOOL

- Sinusoidal PWM (SPWM)
- Modified space vector pulse width modulation

4. MODIFIED THREE PHASE INVERTER CONFIGURATION

The modified circuit consists of three single inverters, they are connected with modified space vector pulse width modulation technique is used for generating

5. LC FILTER CIRCUIT

In order to avoid the harmonic distortion in current, the three phase LC filter circuits are designed the obtained output sinusoidal current will have some low harmonic distortion to avoid this distortion in current LC Filter circuit is used

6. MODIFIED THREE PHASE INVERTER CONFIGURATION

The modified circuit consists of three single inverters, they are connected with modified space vector pulse width modulation technique is used for generating

7. CURRENT CONTROLLER

It is used because of control of steady state error of control system and it is easy to implement.

\[ y(t) = K_p e(t) + K_i \int_0^t e(t) \, dt \]

\[ y(t) = \frac{V_d}{V_q} \]

\[ K_p = \text{proportional Gain} \quad \text{Id} \]

\[ K_i = \text{Integral Gain} \]

\[ \text{Err} = \text{error signal} \]

When does an error signal generate

The Error signal will generate only when there exists a difference instantaneous active current component and reference active current component or vice-versa.

The controller get toned when the proportional gain \( k_p \) is increased to maximum. The steady state error can be eliminated by tuning \( k_i \) integral gain and \( k_p \) proportional gain at the same time.

8. SPACE VECTOR PWM

It is one on the advanced and powerful PWM method. It is more suitable method for variable frequency drive applications. It reduces the
total harmonic distortion and lower order harmonics.

Figure 3

9. PRINCIPLE

It a, b, c ➔ Reference frame

- d-q ➔ Stationary frame

The reference voltage is given as $V_{ref}$.

$V_{ref}$ is obtained by the combination of eight switching patterns ($V_0$ to $V_7$)

The Vector is divided into six equal sectors in a plane

$V_a(t) = V_m \sin wt$

$V_b(t) = V_m \sin (wt - 120^\circ)$

$V_c(t) = V_m \sin (wt + 120^\circ)$

$V_d = \frac{V_{an} - \frac{1}{2} V_{bn} - \frac{1}{2} V_{cn}}{\sqrt{3}/2 V_{bn} - \sqrt{3}/2 V_{cn}}$

$V_{0}, V_{7}$ are two zero vectors. It lies at origin and when no voltage is applied to load. Each sector is divided $60^\circ$ each.

Advantages

1. Reduced switching frequency
2. Less current ripple
3. Output voltage is high
4. Improved harmonic performance

Figure 4

$S_5$ on $S_6$ off

$V_{ref}$ is sampled a regular interval of Time, $T$

$V_{ref}$ is Calculated by Adjacent vectors and Zero Vectors.

$T_0 = T - T_1 - T_2$

$T$ ➔ Sampling period

$V_1, V_2, V_3, V_4, V_5 - V_6$

Are six active vectors it takes the Hexogonal axes.
5. This system is very simple and can be implemented directly to hardware system by means of digital signal processor (DSP)

SIMULATION OF PROPOSED MODIFIED SVPWM SCHEME FOR HYBRID SYSTEM

The simulation model is designed and implemented in Matlab/Simulink environment. Two cases are studied and compared with traditional SVPWM and modified SVPWM scheme. The first case is the system which operates with R load and it has parameters is shown in table 2. Table 3 compares the result of traditional SVPWM and modified SVPWM scheme.
